

# EVAPORATIVE COOLING SYSTEM

## Product Description

An evaporative cooling system for turbine inlet air is a useful option for installations where high ambient temperatures and low relative humidity are common.

The evaporative cooling system will cool compressor intake air through humidification.

The intake air will have a higher relative humidity and lower temperature.

Inlet air cooling will increase the air mass flow rate and pressure ratio, yielding higher turbine output power and efficiency.

The system consists of:

- Evaporative cooling unit bolted to the incoming air face of the filter house.
- A single bank of evaporative cooling media made of corrugated layers of fibrous material, allowing minimal air pressure loss. Water flows down the channels by gravity. The media consists of 2 modules.
- The bottom module features a sump containing the pump and fill valves.
- The upper module has a drain pan and piping to cycle water back to the sump.
- A drift eliminator to limit water entering the turbine.

Some units may have the evaporative cooler pre-installed, others will require the filter house to be opened.

To control the inlet chilling system, GE Vernova will provide a modular hardware style PLC.

Increased Power Output of LM6000 Engine at Various Humidities.

## Customer Value

- Significantly increases turbine power output.
- Increases thermal engine efficiency.
- PLC integrated controls sample weather conditions every 30 seconds, allowing rapid adaptability to changing conditions.
- PLC integrated controls system allows evaporative cooling system to work as a stand alone unit, limiting control integration complexity.
- Only alarm systems need to be integrated in.
- Adaptable to extrinsic control systems.
